Definitions of Managed Objects for APPC using SMIv2

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Table of Contents

1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it defines objects for managing the configuration, monitoring and controlling of network devices with APPC (Advanced Program-to-Program Communications) capabilities. This memo identifies managed objects for the SNA LU6.2 protocols.

2. The SNMP Network Management Framework

The SNMP Network Management Framework consists of several components. For the purpose of this specification, the applicable components of the Framework are the SMI and related documents [2, 3, 4], which define the mechanisms used for describing and naming objects for the

purpose of management.

The Framework permits new objects to be defined for the purpose of experimentation and evaluation.

3. Overview

This document identifies the proposed set of objects for managing the configuration, monitoring and controlling devices with APPC capabilities. APPC is the aspect of SNA which supports peer-to-peer communication, and provides the interface for applications to communicate. In this document, we will describe LU6.2 protocol-specific managed objects.

This document describes both dependent and independent LU 6.2 protocols.

A dependent LU requires assistance from an SSCP in order to activate an LU 6.2 session. An independent LU is able to activate an LU 6.2 session without assistance from the SSCP. If the agent supports dependent LU 6.2 only, the SNA NAU MIB, RFC 1666 [7] is used instead to represent those objects.

Local LUs and partner LUs connect with each other using sessions. Multiple different sessions can be established between LUs with characteristics defined by Modes. Session limits within a defined Mode are negotiated between the local and partner LUs using a protocol called CNOS (Change Number of Sessions).

Transaction Programs (TPs) are applications that use sessions to communicate with each other. Multiple TPs can use the same session, but not at the same time. A single usage of a session is called a conversation. While a session can stay active for a long time, a conversation can come up and down based on usage by the TPs.

Common Programming Interface - Communications (CPI-C) is a standard API (Application Programming Interface) for APPC and OSI TP that is used by TPs for accessing conversations. Although, many of the CPI-C objects in this MIB are relevant to both APPC and OSI TP, the intention is for managing APPC products only.

SNA names such as LU names, CP names, mode names, and COS names can be padded with space characters in SNA formats. These space characters are insignificant. For example, in a BIND RU a mode name of "#INTER" with a length of 6 is identical to a mode name of "#INTER " with a length of 8. However, in this MIB, insignificant space characters are not included by the agent. Using the mode name from the previous example, an agent would return a length of 6 and the

string "#INTER" with no space characters for appcModeAdminModeName, regardless of how it appears in the BIND RU or in internal storage. The lone exception is the all blank mode name, for which the agent returns a length of 8 and the string " " (8 space characterss).

When an SNA name is functioning as a table index, an agent shall treat trailing space characters as significant. If a Management Station requests the objects from a row with index "#INTER ", the agent does not match this to the row with index "#INTER". Since an agent has no insignificant space characters in any of its table indices, the only reason for a Management Station to include them would be to start GetNext processing at a chosen point in a table. For example, a GetNext request with index "M " would start retrieval from a table at the first row with an 8-character index beginning with M or a letter after M.

The SNA/APPC terms and overall architecture are documented in [1], [5], and [6].

Highlights of the management functions supported by the APPC MIB module include the following:

- Activating and deactivating statistics keeping and counting.
- Activating and deactivating tracing.
- Issuing CNOS processing verbs/commands for INITIALIZE_SESSION_LIMIT, CHANGE_SESSION_LIMIT and RESET_SESSION_LIMIT.
- Monitoring of parameters related to local LU, partner LU, modes, TPs and CPI-C side information.
- Deactivating sessions.
- Monitoring of LU6.2-specific session operational parameters and statistics, historical information about abnormally terminated sessions, and information about APPC sessions that are transported by APPN HPR.
- Monitoring of conversation operational parameters, and historical information about abnormally terminated sessions.

This MIB module does not support:

- Modifying APPC defaults.
- Creating and deleting partner LUs, modes, TPs, and CPI-C side information tables.
- Modifying parameters related to local LU, partner LU, modes, TPs, and CPI-C side information.
- Activating or deactivating local LUs.
- Activating or deactivating partner LUs.
- Activating or deactivating conversations.
- Activating or deactivating Transaction Programs.
- Activating sessions.
- Traps

3.1. APPC MIB Structure

The APPC MIB module contains six groups of objects:

- appcGlobal - objects related to global defaults and controls. In addition, CNOS processing objects are also part of this group.
- appcLu - objects related to LU6.2-specific local and partner LU, mode definition, monitoring and control.
- appcTp - objects related to transaction program definition, monitoring and control.
- appcSession - objects related to LU6.2-specific session monitoring.
- appcConversation - objects related to conversation monitoring.
- appcCPIC - objects related to related CPI-C side information.

These groups are described below in more detail.

The objects related to LU6.2 are generally organized into two types of tables: the Admin and Oper tables.

The "Admin" table contains read-only objects which contain default or expected configuration values. This MIB does not create or modify configuration values. The "Oper" table contains objects which provide current operational values, such as state values or negotiated parameters, for dynamic or configured objects. Dynamic objects are created by the APPC system using one of the templates provided in the "Admin" table. Configured objects usually have a one-to-one relationship between "Admin" and "Oper" entries. However, some "Admin" values may have changed since the object became operational, such that the "Oper" values may no longer be based on the "Admin" values. The "Admin" entry could even be deleted. For example, some implementations may allow a mode definition (appcModeAdminEntry) to be deleted even while an active session was using this mode (appcModeOperEntry still exists). Where appropriate, the "Oper" table may include initial starting values for objects that can be reconfigured while operational. How the "Admin" values are changed or deleted is outside the scope of this MIB.

3.1.1. appcGlobal group

The appcGlobal group consists of the following tables and objects:

1) appcCntrlAdminGroup

This group of objects controls whether certain statistics and counters (e.g., session counters and RSCV collection) should be maintained by the Agent. In addition, the ability to activate and deactivate tracing is also supported through objects in this group. These objects are for Agent implementations that wish to provide this level of operational control and are optional.

The objects in this group represent the desired state, with the actual operational values in appcCntlOperGroup.

These objects can be generated initially, after startup of SNA service, by the Agent which uses information from the Node configuration file. Subsequent modifications of object values is possible by a Management station. The modifications to these objects can be saved in the Node configuration file for the next startup (i.e., restart or next initialization) of SNA service, but the mechanism for this function is not defined in this document.

2) appcCntrlOperGroup

This group of objects monitors whether certain statistics and counters (e.g., session counters and RSCV collection) are maintained by an Agent. In addition, the ability to monitor tracing activity is also supported through objects in this group.

This table represents the actual operational state. These states can be modified via objects in the appcCntrlAdminGroup.

3) appcGlobalObjects

These objects describe global information such as APPC system start time, the control point name, and default LU 6.2 configuration values. The type of default configuration information includes mode name, LU, and maximum logical record size.

4) appcCnosControl

These objects allows for issuing of CNOS commands relative to a local and partner LU pair and a Mode. They support the following CNOS commands: INITIALIZE_SESSION_LIMIT, CHANGE_SESSION_LIMIT and RESET_SESSION_LIMIT.

The objects in this group can be modified by a Management Station.

This group consists of objects that are relevant to the CNOS commands parameters, which a Management Station needs to set. After setting the parameters of a CNOS command, the Management Station will set the control object (appcCnosCommand) to request the Agent to issue the appropriate CNOS command.

3.1.2. appcLu group

The appcLu group consists of the following tables:

1) appcLluAdminTable

This table contains objects which describe specific LU6.2 local LU configuration information. The type of information includes the maximum number of sessions supported and compression parameters.

2) appcLluOperTable

This table contains objects which describe specific LU6.2 local LU operational information. The type of information includes the maximum number of sessions supported, the number of sessions currently active, and compression parameters.

3) appcLuPairAdminTable

This table contains objects which describe local LU and partner LU configuration information. The type of information includes security information and whether parallel sessions are supported.

For those implementations that have partner LU definitions associated with each local LU, multiple entries with the same appcLuPairAdminParLuName could exist with different appcLuPairAdminLocLuName. For those implementations in which partner LU definitions apply to all local LUs, the appcLuPairAdminLocLuName is set to '*ALL'.

4) appcLuPairOperTable

This table contains objects which describe partner/local LU pair run-time operational information. The type of information includes security information and whether parallel sessions are supported.

Although the Admin (appcLuPairAdminTable) table entries could be global to all local LUs in a Node, an entry in this Oper table is always associated with one local LU.

A row in this table is created as soon as there is an active session between the local and partner LU. Two entries are present when both LUs in a pair are local.

5) appcModeAdminTable

This table contains objects which describe Mode configuration information. The type of information includes the mode name and maximum session limit.

For those implementations that have Mode definitions associated with each local and partner LU pair, multiple entries with the same appcModeAdminModeName could exist with different appcModeAdminLocLuName and appcModeAdminParLuName. For those implementations in which Mode definitions apply to all local and/or all partner LUs, the appcModeAdminLocLuName and/or appcModeAdminParLuName are set to '*ALL'.

6) appcModeOperTable

This table contains objects which describe Mode run-time operational information for each local/partner LU pair. The type of information includes the mode name and maximum session limit.

Although the Admin table entries could be global to all local and partner LUs in a Node, the Oper table entries are always associated with one local and partner LU pair.

A row in this table is created as soon as there is an active session between local and partner LU for this Mode. Two entries are present when both LUs in a pair are local.

3.1.3. appcTp group

The appcTp group consists of the following table:

1) appcTpAdminTable

This table contains objects which describe transaction program (TP) configuration information. The type of information includes the TP name and TP operation, indicating how the TP will be started.

For those implementations that have TP definitions associated with each local LU, multiple entries with the same appcTpAdminTpName could exist with different appcTpAdminLocLuName. For those implementations in which TP definition applies to all local LUs, it will have appcTpAdminLocLuName set to '*ALL'.

There is no appcTpOperTable. Run-time information about TP tends to be product-specific (e.g., process Id), and much of the information can be derived from the conversation tables.

3.1.4. appcSession group

The appcSession group consists of the following tables:

1) appcActSessTable

This table contains objects which describe LU6.2 session information. The type of information includes the PCID and the pacing counts.

2) appcSessStatsTable

This table contains statistical information about LU 6.2 sessions. The type of information includes counters of bytes and RUs sent and received.

3) appcHistSessTable

This table contains historical information about APPC sessions that have terminated abnormally. The type of information includes the unbind type and sense data.

4) appcSessRtpTable

This table contains information about LU 6.2 sesions that are being transported by High Performance Routing. The type of information includes the NCEID and TCID.

3.1.5. appcConversation group

The appcConversation group consists of the following tables:

1) appcActiveConvTable

This table contains objects which describe active conversation information. The type of information includes the state and type. An entry is created by an Agent when the conversation is started, and is removed when the conversation ends.

2) appcHistConvTable

This table contains objects which describe historical conversation information about abnormally terminated conversations. The number of entries and how long they are kept depends on the Agent implementation. The type of information inclues the sense data and log data.

3.1.6. appcCPIC group

The appcCPIC group consists of the following tables:

1) appcCpicAdminTable

This table contains objects which describe CPI-C side information. The type of information includes the symbolic destination name and partner LU name.

For those implementations that have CPI-C definition associated with each local LU, multiple entries with the same appcCpicAdminSymbDestName could exist with different appcCpicAdminLocLuName. For those implementations in which CPI-C definition applies to all local LUs, it will have appcCpicAdminLocLuName set to '*ALL'.

2) appcCpicOperTable

This table contains objects which describe CPI-C run-time operational information. The type of information includes the symbolic destination name and partner LU name.

                     }
      MAX-ACCESS read-only
      STATUS current
      DESCRIPTION
          "Specifies how the program will be started.

              other - Specifies that the default TP operation is none of
                      the methods specified below. It may be a
                      product-specific method.

              queuedOperatorStarted - Specifies that one version of the
                      program will be run at a time.  If an incoming
                      attach arrives and the program has not been started
                      yet, APPC will issue a message to the operator to
                      start the specified program.  Subsequent attaches
                      that arrive while the program is active will be
                      queued.

              queuedOperatorPreloaded - Specifies that one version
```

```
                    of the program will be run at a time.  If an
                    incoming attach arrives and the program has not
                    been started yet, the Attach will be rejected.  The
                    APPC attach manager determines that a TP has
                    started upon reception of an APPC RECEIVE_ALLOCATE
                    verb, or a CPI-C Accept_Conversation (CMACCP) or
                    Specify_Local_TP_Name (CMSLTP) call.  No message is
                    sent to the operator.  Subsequent attaches that
                    arrive while the program is active are queued.

            queuedAmStarted - Specifies that one version of the
                    program will be run at a time and will be started
                    by the APPC attach manager.  Subsequent attaches
                    that arrive while the program is active will be
                    queued.

            nonqueuedAmStarted - Specifies that multiple copies of
                    the program will be run at a time and will be
                    started by the APPC attach manager. "

      STATUS current
      DESCRIPTION
          "Specifies the name of the transaction program (TP) to be
          invoked when a session using this mode is deactivated or ended.
          If no such TP is defined, this object is a null string.  When
          the TP name consists entirely of displayable EBCDIC code
          points, it is mapped directly to the equivalent ASCII display
          string.  However, registered TP names always have a non-
          displayable EBCDIC code point (value less than or equal to
          x'3F') as the first character, so they cannot be directly
          mapped to an ASCII display string.  These TP names are
          converted to a display string that is equivalent to a
          hexadecimal display of the EBCDIC code points.  For example,
          the 2-byte TP name x'06F1' (CNOS) is converted to the 6-byte
          ASCII display string '06F1' (including the two single quotes).

                      secondaryOnly(4),
                      primaryOrSecondary(5)
                     }
      MAX-ACCESS read-only
      STATUS current
      DESCRIPTION
          "Specifies the responsibility for session reinitiation of a
          single session with the partner LU (when the session goes
          down).  The local LU uses this parameter to specify the session
          reinitiation responsibility in session activation (SNA BIND)
          requests and responses.

                notApplicable      - specifies that this parameter has
                                     no meaning since the value of
                                     appcLuPairAdminParaSessSup is yes.
                                     The field in the SNA BIND is
                                     reserved (set to zero).
                operatorControlled - specifies that neither LU will
                                     automatically attempt to reinitiate
                                     the session.  The operator on either
                                     side will manually reactivate the
                                     session.  A contention race (both
                                     side reinitiating at the same time)
                                     is won by the LU with the
                                     lexicographically greater fully-
                                     qualified LU name.
                primaryOnly        - specifies that the primary LU will
```

```
                                    automatically attempt to reinitiate
                                    the session.
                secondaryOnly      - specifies that the secondary LU will
                                    automatically attempt to reinitiate
                                    the session.
                primaryOrSecondary - specifies that either the primary or
                                    the secondary may automatically
                                    attempt to reinitiate the session.
                                    A contention race is handled the
                                    same way as with operatorControlled.

      STATUS current
      DESCRIPTION
```

```
            "Specifies the name of the transaction program (TP) to be
            invoked when a session using this mode is deactivated or ended.
            If the name is NULL, no transaction program is invoked.  When
            the TP name consists entirely of displayable EBCDIC code
            points, it is mapped directly to the equivalent ASCII display
            string.  However, registered TP names always have a non-
            displayable EBCDIC code point (value less than or equal to
            x'3F') as the first character, so they cannot be directly
            mapped to an ASCII display string.  These TP names are
            converted to a display string that is equivalent to a
            hexadecimal display of the EBCDIC code points.  For example,
            the 2-byte TP name x'06F1' (CNOS) is converted to the 6-byte
            ASCII display string '06F1' (including the two single quotes)."

                    primaryOrSecondary(5)
                   }
      MAX-ACCESS read-only
      STATUS current
      DESCRIPTION
          "Specifies the responsibility for session reinitiation of a
          single session with the partner LU (when the session goes
          down).  The local LU uses this parameter to specify the session
          reinitiation responsibility in session activation (SNA BIND)
          requests and responses.

                notApplicable      - specifies that this parameter has
                                     no meaning since the value of
                                     appcLuPairOperParaSessSup is yes.
                                     The field in the SNA BIND is
                                     reserved (set to zero).
                operatorControlled - specifies that neither LU will
                                     automatically attempt to reinitiate
                                     the session.  The operator on either
                                     side will manually reactivate the
                                     session.  A contention race (both
                                     side reinitiating at the same time)
                                     is won by the LU with the
                                     lexicographically greater fully-
                                     qualified LU name.
                primaryOnly        - specifies that the primary LU will
                                     automatically attempt to reinitiate
                                     the session.
                secondaryOnly      - specifies that the secondary LU will
                                     automatically attempt to reinitiate
                                     the session.
                primaryOrSecondary - specifies that either the primary or
                                     the secondary may automatically
                                     attempt to reinitiate the session.
                                     A contention race is handled the
                                     same way as with operatorControlled.

appcTpAdminTpName OBJECT-TYPE
      SYNTAX DisplayString (SIZE (1..64))
      MAX-ACCESS not-accessible
      STATUS current
      DESCRIPTION
          "The local transaction program name. This name is sent on an
           ATTACH remote allocation request.

           When the TP name consists entirely of displayable EBCDIC
           code points, it is mapped directly to the equivalent ASCII
           display string.  However, registered TP names always have a
           non-displayable EBCDIC code point (value less than or equal to
           x'3F') as the first character, so they cannot be directly
           mapped to an ASCII display string.  These TP names are
           converted to a display string that is equivalent to a
           hexadecimal display of the EBCDIC code points.  For example,
           the 2-byte TP name x'06F1' (CNOS) is converted to the 6-byte
           ASCII display string '06F1' (including the two single quotes)."

                      queuedOperatorPreloaded(3),
                      queuedAmStarted(4),
                      nonqueuedAmStarted(5)
                     }
      MAX-ACCESS read-only
      STATUS current
      DESCRIPTION
          "Specifies how the program will be started.
              other - Specifies that the program operation is none of
                      the methods specified. It may be a
                      product-specific method.

              queuedOperatorStarted - Specifies that one version of the
                      program will be run at a time.  If an incoming
                      attach arrives and the program has not been started
                      yet, APPC will issue a message to the operator to
                      start the specified program.  Subsequent attaches
                      that arrive while the program is active will be
                      queued.

              queuedOperatorPreloaded - Specifies that one version of the
                      program will be run at a time.  If an incoming
                      attach arrives and the program has not been started
                      yet, the Attach will be rejected.  The APPC attach
                      manager determines that a TP has started upon
                      reception of an APPC RECEIVE_ALLOCATE verb, or a
                      CPI-C Accept_Conversation (CMACCP) or
                      Specify_Local_TP_Name (CMSLTP) call.  No message is
                      sent to the operator.  Subsequent attaches that
                      arrive while the program is active are queued.

              queuedAmStarted - Specifies that one version of the
                      program will be run at a time and will be started
                      by the APPC attach manager.  Subsequent attaches
```

```
                    that arrive while the program is active will be
                    queued.

                nonqueuedAmStarted - Specifies that multiple copies of the
                    program will be run at a time and will be started
                    by the APPC attach manager."

appcActSessOperState OBJECT-TYPE
      SYNTAX INTEGER {
                      unbound (1),
                      pendingBind (2),
                      bound (3),
                      pendingUnbind (4)
                     }
      MAX-ACCESS read-write
      STATUS current
      DESCRIPTION
          "The value indicates the current operational state of the
          session.

                  'unbound (1)' - session has been  unbound;
                        in this state it will be removed from the
                        session table by the Agent.

                  'pendingBind (2)' - this state has different
                        meanings for dependent and independent LUs;
```

```
                        for dependent LU - waiting for BIND from
                        the host, for independent LU - waiting for
                        BIND response.  When a session enters this
                        state, the corresponding entry in the
                        session table is created by the Agent.

                    'bound (3)' - session has been successfully bound.

                    'pendingUnbind (4)' - session enters this state
                         when an UNBIND is sent and before the
                         rsp(UNBIND) is received.

            Session deactivation:

                    If a session is in the operational state
                    'bound (3)' then setting the value of this
                    object to 'unbound (1)' will initiate the
                    session shutdown.

                    If a session is in the operational state
                    'pendingBind (2)' then setting the value of this
                    object to 'unbound (1)' will initiate the session
                    shutdown.

                    If a session is in the operational state
                    'pendingUnbind (4)' for an abnormally long period
                    of time (e.g., three minutes) then setting the value
                    of this object to 'unbound (1)' will change the
                    session operational state to 'unbound (1)'. "

      DESCRIPTION
          "Indicates the state of the conversation at the instant when
          the information was retrieved.  The values are:
```

reset
The conversation is reset (i.e., deallocated).
send
The conversation can send data. This value also is returned if the conversation is in Send-Pending state.
receive
The conversation can receive data.
confirm
The conversation has received a confirm indicator. It can issue an [MC_]CONFIRMED or [MC_]SEND_ERROR verb to change state. It will continue in Receive state if an [MC_]CONFIRMED verb is issued.
confirmSend
The conversation is in Confirm state and changes to Send state when an [MC_]CONFIRMED verb is issued.
confirmDealloc
The conversation is in Confirm state and becomes inactive when an [MC_]CONFIRMED verb is issued.
pendingDeallocate
The conversation is in Pending-Deallocate state while it waits for (MC_)DEALLOCATE TYPE (sync_level) to complete.
pendingPost
The conversation is in Pending-Post state while it waits for the [MC_]RECEIVE_AND_POST verb to complete its receive function.
sendReceive
The full-duplex conversation can send or receive data.
sendOnly
The full-duplex conversation can send data, but it does not have permission to receive data, because the partner TP has already deallocated its side of the conversation.
receiveOnly
The full-duplex conversation can receive data, but it does not have permission to send data, because it has already deallocated its side of the conversation.
deferReceive
Waiting for a successful SYNCPT verb operation to go into the receive state.
deferDeallocate
Waiting for a successful SYNCPT verb operation to go into the reset state.

```
                syncpoint
                          Need to response to a SYNCPT verb issued.  After
                          successful operation, the next state will be
                          receive.
                syncpointSend
                          Need to response to a SYNCPT verb issued.  After
                          successful operation, the next state will be
