

## Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations

### Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

### Abstract

This memo defines Management Information Bases (MIBs) for performing remote ping, traceroute and lookup operations at a remote host. When managing a network it is useful to be able to initiate and retrieve the results of ping or traceroute operations when performed at a remote host. A Lookup capability is defined in order to enable resolving of either an IP address to an DNS name or an DNS name to an IP address at a remote host.

Currently, there are several enterprise-specific MIBs for performing remote ping or traceroute operations. The purpose of this memo is to define a standards-based solution to enable interoperability.

## 1.0 Introduction

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#), reference [13].

This document is a product of the Distributed Management (DISMAN) Working Group. Its purpose is to define standards-based MIB modules for performing specific remote operations. The remote operations defined by this document consist of the ping, traceroute and lookup functions.

Ping and traceroute are two very useful functions for managing networks. Ping is typically used to determine if a path exists between two hosts while traceroute shows an actual path. Ping is usually implemented using the Internet Control Message Protocol (ICMP) "ECHO" facility. It is also possible to implement a ping capability using alternate methods, some of which are:

- o Using the UDP echo port (7), if supported.

This is defined by [RFC 862](#) [2].

- o Timing an SNMP query.
- o Timing a TCP connect attempt.

In general, almost any request/response flow can be used to generate a round-trip time. Often many of the non-ICMP ECHO facility methods stand a better chance of yielding a good response (not timing out for

example) since some routers don't honor Echo Requests (timeout situation) or they are handled at lower priority, hence possibly giving false indications of round trip times.

It must be noted that almost any of the various methods used for generating a round-trip time can be considered a form of system attack when used excessively. Sending a system requests too often can negatively effect its performance. Attempting to connect to what is supposed to be an unused port can be very unpredictable. There are tools that attempt to connect to a range of TCP ports to test that any receiving server can handle erroneous connection attempts.

It also is important to the management application using a remote ping capability to know which method is being used. Different methods will yield different response times since the protocol and resulting processing will be different. It is RECOMMENDED that the ping capability defined within this memo be implemented using the ICMP Echo Facility.

Traceroute is usually implemented by transmitting a series of probe packets with increasing time-to-live values. A probe packet is a UDP datagram encapsulated into an IP packet. Each hop in a path to the target (destination) host rejects the probe packet (probe's TTL too small) until its time-to-live value becomes large enough for the probe to be forwarded. Each hop in a traceroute path returns an ICMP message that is used to discover the hop and to calculate a round trip time. Some systems use ICMP probes (ICMP Echo request packets) instead of UDP ones to implement traceroute. In both cases traceroute relies on the probes being rejected via an ICMP message to discover the hops taken along a path to the final destination. Both probe types, UDP and ICMP, are encapsulated into an IP packet and thus have a TTL field that can be used to cause a path rejection.

Implementations of the remote traceroute capability as defined within this memo SHOULD be done using UDP packets to a (hopefully) unused port. ICMP probes (ICMP Echo Request packets) SHOULD NOT be used. Many PC implementations of traceroute use the ICMP probe method, which they should not, since this implementation method has been known to have a high probability of failure. Intermediate hops become invisible when a router either refuses to send an ICMP TTL expired message in response to an incoming ICMP packet or simply tosses ICMP echo requests altogether.

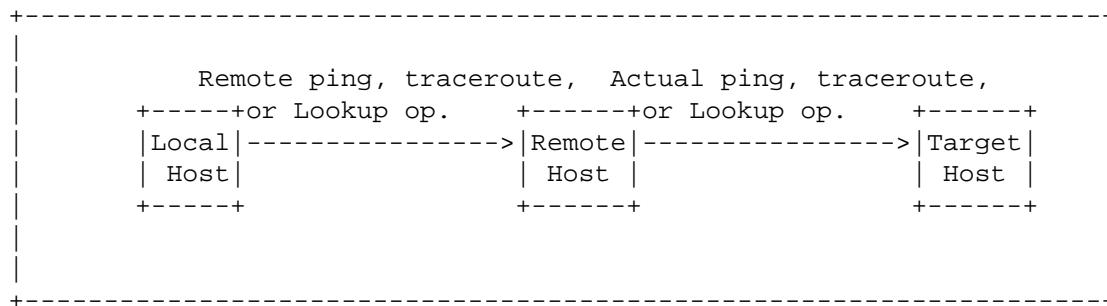

The behavior of some routers not to return a TTL expired message in response to an ICMP Echo request is due in part to the following text extracted from [RFC 792](#) [20]:

"The ICMP messages typically report errors in the processing of datagrams. To avoid the infinite regress of messages about messages etc., no ICMP messages are sent about ICMP messages."

Both ping and traceroute yield round-trip times measured in milliseconds. These times can be used as a rough approximation for network transit time.

The Lookup operation enables the equivalent of either a `gethostbyname()` or a `gethostbyaddr()` call being performed at a remote host. The Lookup `gethostbyname()` capability can be used to determine the symbolic name of a hop in a traceroute path.

Consider the following diagram:

A local host is the host from which the remote ping, traceroute, or Lookup operation is initiated using an SNMP request. The remote host is a host where the MIBs defined by this memo are implemented that receives the remote operation via SNMP and performs the actual ping, traceroute, or lookup function.

## 2.0 The SNMP Network Management Framework

The SNMP Management Framework presently consists of five major components:

- o An overall architecture, described in [RFC 2571](#) [7].
- o Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIv1 and described in STD 16, [RFC 1155](#) [14], STD 16, [RFC 1212](#) [15] and [RFC 1215](#) [16]. The second version, called SMIv2, is described in STD 58, [RFC 2578](#) [3], STD 58, [RFC 2579](#) [4] and STD 58, [RFC 2580](#) [5].

- o Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in STD 15, RFC 1157 [1]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in RFC 1901 [17] and RFC 1906 [18]. The third version of the message protocol is called SNMPv3 and described in RFC 1906 [18], RFC 2572 [8] and RFC 2574 [10].
- o Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [1]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [6].
- o A set of fundamental applications described in RFC 2573 [9] and the view-based access control mechanism described in RFC 2575 [11].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

This memo specifies MIB modules that are compliant to the SMIV2. A MIB conforming to the SMIV1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIV2 will be converted into textual descriptions in SMIV1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB.

### 3.0 Structure of the MIBs

This document defines three MIB modules:

- o DISMAN-PING-MIB  
Defines a ping MIB.
- o DISMAN-TRACEROUTE-MIB  
Defines a traceroute MIB.

- o DISMAN-NSLOOKUP-MIB

Provides access to the resolver `gethostbyname()` and `gethostbyaddr()` functions at a remote host.

The ping and traceroute MIBs are structured to allow creation of ping or traceroute tests that can be set up to periodically issue a series of operations and generate NOTIFICATIONS to report on test results. Many network administrators have in the past written UNIX shell scripts or command batch files to operate in fashion similar to the functionality provided by the ping and traceroute MIBs defined within this memo. The intent of this document is to acknowledge the importance of these functions and to provide a standards-based solution.

### 3.1 Ping MIB

The DISMAN-PING-MIB consists of the following components:

- o `pingMaxConcurrentRequests`
- o `pingCtlTable`
- o `pingResultsTable`
- o `pingProbeHistoryTable`

#### 3.1.1 `pingMaxConcurrentRequests`

The object `pingMaxConcurrentRequests` enables control of the maximum number of concurrent active requests that an agent implementation supports. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

#### 3.1.2 `pingCtlTable`

A remote ping test is started by setting `pingCtlAdminStatus` to `enabled(1)`. The corresponding `pingCtlEntry` MUST have been created and its `pingCtlRowStatus` set to `active(1)` prior to starting the test. A single SNMP PDU can be used to create and start a remote ping test. Within the PDU, `pingCtlTargetAddress` should be set to the target host's address (`pingCtlTargetAddressType` will default to `ipv4(1)`), `pingCtlAdminStatus` to `enabled(1)`, and `pingCtlRowStatus` to `createAndGo(4)`.

The first index element, `pingCtlOwnerIndex`, is of type `SnmpAdminString`, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 2575 [11], VACM) and allows a management application to identify its entries. The second index, `pingCtlTestName` (also an `SnmpAdminString`), enables the same management application to have multiple requests outstanding.

Using the maximum value for the parameters defined within a `pingEntry` can result in a single remote ping test taking at most 15 minutes (`pingCtlTimeOut` times `pingCtlProbeCount`) plus whatever time it takes to send the ping request and receive its response over the network from the target host. Use of the defaults for `pingCtlTimeOut` and `pingCtlProbeCount` yields a maximum of 3 seconds to perform a "normal" ping test.

A management application can delete an active remote ping request by setting the corresponding `pingCtlRowStatus` object to `destroy(6)`.

The contents of the `pingCtlTable` is preserved across reIPLs (Initial Program Loads) of its agent according to the values of each of the `pingCtlStorageType` objects.

### 3.1.3 pingResultsTable

An entry in the `pingResultsTable` is created for a corresponding `pingCtlEntry` once the test defined by this entry is started.

### 3.1.4 pingProbeHistoryTable

The results of past ping probes can be stored in this table on a per `pingCtlEntry` basis. This table is initially indexed by `pingCtlOwnerIndex` and `pingCtlTestName` in order for the results of a probe to relate to the `pingCtlEntry` that caused it. The maximum number of entries stored in this table per `pingCtlEntry` is determined by the value of `pingCtlMaxRows`.

An implementation of this MIB will remove the oldest entry in the `pingProbeHistoryTable` to allow the addition of a new entry once the number of rows in the `pingProbeHistoryTable` reaches the value specified by `pingCtlMaxRows`. An implementation MUST start assigning `pingProbeHistoryIndex` values at 1 and wrap after exceeding the maximum possible value as defined by the limit of this object (`'ffffffff'h`).

### 3.2 Traceroute MIB

The DISMAN-TRACEROUTE-MIB consists of the following components:

- o traceRouteMaxConcurrentRequests
- o traceRouteCtlTable
- o traceRouteResultsTable
- o traceRouteProbeHistoryTable
- o traceRouteHopsTable

#### 3.2.1 traceRouteMaxConcurrentRequests

The object traceRouteMaxConcurrentRequests enables control of the maximum number of concurrent active requests that an agent implementation supports. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

#### 3.2.2 traceRouteCtlTable

A remote traceroute test is started by setting traceRouteCtlAdminStatus to enabled(1). The corresponding traceRouteCtlEntry MUST have been created and its traceRouteCtlRowStatus set to active(1) prior to starting the test. A single SNMP PDU can be used to create and start a remote traceroute test. Within the PDU, traceRouteCtlTargetAddress should be set to the target host's address (traceRouteCtlTargetAddressType will default to ipv4(1)), traceRouteCtlAdminStatus to enabled(1), and traceRouteCtlRowStatus to createAndGo(4).

The first index element, traceRouteCtlOwnerIndex, is of type SnmpAdminString, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 2575 [11], VACM) and allows a management application to identify its entries. The second index, traceRouteCtlTestName (also an SnmpAdminString), enables the same management application to have multiple requests outstanding.

Traceroute has a much longer theoretical maximum time for completion than ping. Basically 42 hours and 30 minutes (the product of traceRouteCtlTimeOut, traceRouteCtlProbesPerHop, and traceRouteCtlMaxTtl) plus some network transit time! Use of the defaults defined within an traceRouteCtlEntry yields a maximum of 4 minutes and 30 seconds for a default traceroute operation. Clearly

42 plus hours is too long to wait for a traceroute operation to complete.

The maximum TTL value in effect for traceroute determines how long the traceroute function will keep increasing the TTL value in the probe it transmits hoping to reach the target host. The function ends whenever the maximum TTL is exceeded or the target host is reached. The object `traceRouteCtlMaxFailures` was created in order to impose a throttle for how long traceroute continues to increase the TTL field in a probe without receiving any kind of response (timeouts). It is RECOMMENDED that agent implementations impose a time limit for how long it allows a traceroute operation to take relative to how the function is implemented. For example, an implementation that can't process multiple traceroute operations at the same time SHOULD impose a shorter maximum allowed time period.

A management application can delete an active remote traceroute request by setting the corresponding `traceRouteCtlRowStatus` object to `destroy(6)`.

The contents of the `traceRouteCtlTable` is preserved across reIPLs (Initial Program Loads) of its agent according to the values of each of the `traceRouteCtlStorageType` objects.

### 3.2.3 `traceRouteResultsTable`

An entry in the `traceRouteResultsTable` is created upon determining the results of a specific traceroute operation. Entries in this table relate back to the `traceRouteCtlEntry` that caused the corresponding traceroute operation to occur. The objects `traceRouteResultsCurHopCount` and `traceRouteResultsCurProbeCount` can be examined to determine how far the current remote traceroute operation has reached.

### 3.2.4 `traceRouteProbeHistoryTable`

The results of past traceroute probes can be stored in this table on a per `traceRouteCtlEntry` basis. This table is initially indexed by `traceRouteCtlOwnerIndex` and `traceRouteCtlTestName` in order for the results of a probe to relate to the `traceRouteCtlEntry` that caused it. The number of entries stored in this table per `traceRouteCtlEntry` is determined by the value of `traceRouteCtlMaxRows`.

An implementation of this MIB will remove the oldest entry in the `traceRouteProbeHistoryTable` to allow the addition of a new entry once the number of rows in the `traceRouteProbeHistoryTable` reaches the value of `traceRouteCtlMaxRows`. An implementation MUST start

assigning `traceRouteProbeHistoryIndex` values at 1 and wrap after exceeding the maximum possible value as defined by the limit of this object ('ffffffff'h).

### 3.2.5 `traceRouteHopsTable`

The current traceroute path can be stored in this table on a per `traceRouteCtlEntry` basis. This table is initially indexed by `traceRouteCtlOwnerIndex` and `traceRouteCtlTestName` in order for a traceroute path to relate to the `traceRouteCtlEntry` that caused it. A third index, `traceRouteHopsHopIndex`, enables keeping one `traceRouteHopsEntry` per traceroute hop. Creation of `traceRouteHopsTable` entries is enabled by setting the corresponding `traceRouteCtlCreateHopsEntries` object to `true(1)`.

## 3.3 Lookup MIB

The DISMAN-NSLOOKUP-MIB consists of the following components:

- o `lookupMaxConcurrentRequests`, and `lookupPurgeTime`
- o `lookupCtlTable`
- o `lookupResultsTable`

### 3.3.1 `lookupMaxConcurrentRequests` and `lookupPurgeTime`

The object `lookupMaxConcurrentRequests` enables control of the maximum number of concurrent active requests that an agent implementation is structured to support. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

The object `lookupPurgeTime` provides a method for entries in the `lookupCtlTable` and `lookupResultsTable` to be automatically deleted after the corresponding operation completes.

### 3.3.2 `lookupCtlTable`

A remote lookup operation is initiated by performing an SNMP SET request on `lookupCtlRowStatus`. A single SNMP PDU can be used to create and start a remote lookup operation. Within the PDU, `lookupCtlTargetAddress` should be set to the entity to be resolved (`lookupCtlTargetAddressType` will default to `ipv4(1)`) and `lookupCtlRowStatus` to `createAndGo(4)`. The object `lookupCtlOperStatus`

can be examined to determine the state of an lookup operation. A management application can delete an active remote lookup request by setting the corresponding `lookupCtlRowStatus` object to `destroy(6)`.

An `lookupCtlEntry` is initially indexed by `lookupCtlOwnerIndex`, which is of type `SnmpAdminString`, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 2575 [11], VACM) and also allows for a management application to identify its entries. The `lookupCtlOwnerIndex` portion of the index is then followed by `lookupCtlOperationName`. The `lookupCtlOperationName` index enables the same `lookupCtlOwnerIndex` entity to have multiple outstanding requests.

The value of `lookupCtlTargetAddressType` determines which lookup function to perform. Specification of `dns(16)` as the value of this index implies that the `gethostbyname` function should be performed to determine the numeric addresses associated with a symbolic name via `lookupResultsTable` entries. Use of a value of either `ipv4(1)` or `ipv6(2)` implies that the `gethostbyaddr` function should be performed to determine the symbolic name(s) associated with a numeric address at a remote host.

### 3.3.3 lookupResultsTable

The `lookupResultsTable` is used to store the results of lookup operations. The `lookupResultsTable` is initially indexed by the same index elements that the `lookupCtlTable` contains (`lookupCtlOwnerIndex` and `lookupCtlOperationName`) but has a third index element, `lookupResultsIndex` (Unsigned32 textual convention), in order to associate multiple results with the same `lookupCtlEntry`.

Both the `gethostbyname` and `gethostbyaddr` functions typically return a pointer to a `hostent` structure after being called. The `hostent` structure is defined as:

```
struct hostent {
    char  *h_name;      /* official host name      */
    char  *h_aliases[]; /* list of other aliases  */
    int   h_addrtype;   /* host address type      */
    int   h_length;     /* length of host address */
    char  **h_addr_list; /* list of address for host */
};
```

The `hostent` structure is listed here in order to address the fact that a remote host can be multi-homed and can have multiple symbolic (DNS) names. It is not intended to imply that implementations of the DISMAN-LOOKUP-MIB are limited to systems where the `hostent` structure is supported.

The `gethostbyaddr` function is called with a host address as its parameter and is used primarily to determine a symbolic name to associate with the host address. Entries in the `lookupResultsTable` MUST be made for each host name returned. The official host name MUST be assigned a `lookupResultsIndex` of 1.

The `gethostbyname` function is called with a symbolic host name and is used primarily to retrieve a host address. Normally, the first `h_addr_list` host address is considered to be the primary address and as such is associated with the symbolic name passed on the call.

Entries MUST be stored in the `lookupResultsTable` in the order that they are retrieved. Values assigned to `lookupResultsIndex` MUST start at 1 and increase in order.

An implementation SHOULD NOT retain SNMP-created entries in the `lookupTable` across `reIPLs` (Initial Program Loads) of its agent, since management applications need to see consistent behavior with respect to the persistence of the table entries that they create.

-- Textual Conventions

OperationResponseStatus ::= TEXTUAL-CONVENTION

STATUS current

DESCRIPTION

"Used to report the result of an operation:

responseReceived(1) - Operation completes successfully.

unknown(2) - Operation failed due to unknown error.

internalError(3) - An implementation detected an error in its own processing that caused an operation to fail.

requestTimedOut(4) - Operation failed to receive a valid reply within the time limit imposed on it.

unknownDestinationAddress(5) - Invalid destination address.

noRouteToTarget(6) - Could not find a route to target.

interfaceInactiveToTarget(7) - The interface to be used in sending a probe is inactive without an alternate route existing.

arpFailure(8) - Unable to resolve a target address to a media specific address.

maxConcurrentLimitReached(9) - The maximum number of concurrent active operations would have been exceeded if the corresponding operation was allowed.

unableToResolveDnsName(10) - The DNS name specified was unable to be mapped to an IP address.

invalidHostAddress(11) - The IP address for a host

has been determined to be invalid. Examples of this are broadcast or multicast addresses."

```

pingCtlOwnerIndex OBJECT-TYPE

SYNTAX SnmpAdminString (SIZE(0..32))

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model ([RFC 2575](#), VACM) for tables in which multiple users may need to independently create or modify entries, the initial index is used as an 'owner

index'. Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

pingCtlByPassRouteTable OBJECT-TYPE

SYNTAX TruthValue

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"The purpose of this object is to optionally enable bypassing the route table. If enabled, the remote host will bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an

error is returned. This option can be used to perform the ping operation to a local host through an interface that has no route defined (e.g., after the interface was dropped by routed)."

DEFVAL { false }  
::= { pingCtlEntry 21 }

pingCtlDSField OBJECT-TYPE

SYNTAX Unsigned32 (0..255)  
MAX-ACCESS read-create  
STATUS current

DESCRIPTION

"Specifies the value to store in the Differentiated Services (DS) Field in the IP packet used to encapsulate the ping probe. The DS Field is defined as the Type of Service (TOS) octet in a IPv4 header or as the Traffic Class octet in a IPv6 header.

The value of this object must be a decimal integer in the range from 0 to 255. This option can be used to determine what effect an explicit DS Field setting has on a ping response. Not all values are legal or meaningful. A value of 0 means that the function represented by this option is not supported. DS Field usage is often not supported by IP implementations and not all values are supported. Refer to [RFC 2474](#) for guidance on usage of this field."

REFERENCE

"Refer to [RFC 2474](#) for the definition of the Differentiated Services Field and to [RFC 1812 Section 5.3.2](#) for Type of Service (TOS)."

DEFVAL { 0 }  
::= { pingCtlEntry 22 }

pingCtlRowStatus OBJECT-TYPE

SYNTAX RowStatus  
MAX-ACCESS read-create  
STATUS current

DESCRIPTION

"This object allows entries to be created and deleted in the pingCtlTable. Deletion of an entry in this table results in all corresponding (same pingCtlOwnerIndex and pingCtlTestName index values) pingResultsTable and pingProbeHistoryTable entries being deleted.

A value MUST be specified for pingCtlTargetAddress prior to a transition to active(1) state being

accepted.

Activation of a remote ping operation is controlled via pingCtlAdminStatus and not by changing this object's value to active(1).

Transitions in and out of active(1) state are not allowed while an entry's pingResultsOperStatus is active(1) with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active ping operation.

The operational state of a ping operation can be determined by examination of its pingResultsOperStatus object."

#### REFERENCE

"See definition of RowStatus in RFC 2579, 'Textual Conventions for SMIV2.'"

STATUS current

DESCRIPTION

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (RFC 2575, VACM) for tables in which multiple users may need to independently create or modify entries, the initial index is used as an 'owner index'. Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

traceRouteCtlDSField OBJECT-TYPE

SYNTAX Unsigned32 (0..255)  
MAX-ACCESS read-create  
STATUS current  
DESCRIPTION  
"Specifies the value to store in the Differentiated Services (DS) Field in the IP packet used to encapsulate the traceroute probe. The DS Field is defined as the Type of Service (TOS) octet in a IPv4 header or as the Traffic Class octet in a IPv6 header.

The value of this object must be a decimal integer in the range from 0 to 255. This option can be used to determine what effect an explicit DS Field setting has on a traceroute response. Not all values are legal or meaningful. DS Field usage is often not supported by IP implementations. A value of 0 means that the function represented by this option is not supported. Useful TOS octet values are probably '16' (low delay) and '8' (high throughput)."

REFERENCE

"Refer to [RFC 2474](#) for the definition of the Differentiated Services Field and to [RFC 1812 Section 5.3.2](#) for Type of Service (TOS)."

DESCRIPTION

"The value of this object is used either to report or select the implementation method to be used for performing a traceroute operation. The value of this object may be selected from traceRouteImplementationTypeDomains.

Additional implementation types should be allocated as required by implementers of the DISMAN-TRACEROUTE-MIB under their enterprise specific registration point and not beneath traceRouteImplementationTypeDomains."

DEFVAL { traceRouteUsingUdpProbes }

```
::= { traceRouteCtlEntry 26 }
```

traceRouteCtlRowStatus OBJECT-TYPE

SYNTAX RowStatus

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"This object allows entries to be created and deleted in the traceRouteCtlTable. Deletion of an entry in this table results in all corresponding (same traceRouteCtlOwnerIndex and traceRouteCtlTestName index values) traceRouteResultsTable, traceRouteProbeHistoryTable, and traceRouteHopsTable entries being deleted.

A value **MUST** be specified for traceRouteCtlTargetAddress prior to a transition to active(1) state being accepted.

Activation of a remote traceroute operation is controlled via traceRouteCtlAdminStatus and not by transitioning of this object's value to active(1).

Transitions in and out of active(1) state are not allowed while an entry's traceRouteResultsOperStatus is active(1) with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active traceroute operation.

The operational state of an traceroute operation can be determined by examination of the corresponding traceRouteResultsOperStatus object."

#### REFERENCE

"See definition of RowStatus in [RFC 2579](#), 'Textual Conventions for SMIv2.'"

```

```
lookupCtlEntry OBJECT-TYPE
    SYNTAX      LookupCtlEntry
    MAX-ACCESS  not-accessible
    STATUS      current
    DESCRIPTION
        "Defines an entry in the lookupCtlTable.  A
        lookupCtlEntry is initially indexed by
        lookupCtlOwnerIndex, which is of type SnmpAdminString,
        a textual convention that allows for use of the SNMPv3
        View-Based Access Control Model (RFC 2575 [11], VACM)
        and also allows an management application to identify
        its entries.  The second index element,
        lookupCtlOperationName, enables the same
        lookupCtlOwnerIndex entity to have multiple outstanding
        requests.

        The value of lookupCtlTargetAddressType determines which
        lookup function to perform.  Specification of dns(16)
```

as the value of this index implies that the `gethostbyname` function should be performed to determine the numeric addresses associated with a symbolic name via `lookupResultsTable` entries. Use of a value of either `ipv4(1)` or `ipv6(2)` implies that the `gethostbyaddr` function should be performed to determine the symbolic name(s) associated with a numeric address at a remote host."

```

lookupCtlOwnerIndex OBJECT-TYPE

SYNTAX SnmpAdminString (SIZE(0..32))

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (RFC 2575, VACM) for tables in which multiple users may need to independently create or modify entries, the initial index is used as an 'owner index'. Such an initial index has a syntax of `SnmpAdminString`, and can thus be trivially mapped to a `securityName` or `groupName` as defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this

portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

::= { lookupCtlEntry 1 }

lookupCtlOperationName OBJECT-TYPE

SYNTAX SnmpAdminString (SIZE(0..32))

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"The name of a lookup operation. This is locally unique, within the scope of an lookupCtlOwnerIndex."

::= { lookupCtlEntry 2 }

lookupCtlTargetAddressType OBJECT-TYPE

SYNTAX InetAddressType

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"Specifies the type of address for either performing a gethostbyname or a gethostbyaddr function at a remote host. Specification of dns(16) as the value for this object means that the gethostbyname function should be performed to return one or more numeric addresses. Use of a value of either ipv4(1) or ipv6(2) means that the gethostbyaddr function should be used to return the symbolic names associated with a remote host."

::= { lookupCtlEntry 3 }

lookupCtlTargetAddress OBJECT-TYPE

SYNTAX InetAddress

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"Specifies the address used for a resolver lookup at a remote host. The corresponding lookupCtlAddressType objects determines its type as well as the function that can be requested."

A value for this object MUST be set prior to transitioning its corresponding lookupCtlEntry to active(1) via lookupCtlRowStatus."

::= { lookupCtlEntry 4 }

lookupCtlOperStatus OBJECT-TYPE

SYNTAX           INTEGER {  
                  notStarted(2), -- operation has not started  
                  completed(3)   -- operation is done  
                  }  
MAX-ACCESS       read-only  
STATUS           current  
DESCRIPTION  
    "Reflects the operational state of an lookupCtlEntry:  
  
        enabled(1)     - Operation is active.  
        notStarted(2) - Operation has not been enabled.  
        completed(3)  - Operation has completed.  
  
    An operation is automatically enabled(1) when its  
    lookupCtlRowStatus object is transitioned to active(1)  
    status.  Until this occurs lookupCtlOperStatus MUST  
    report a value of notStarted(2).  After the lookup  
    operation completes (success or failure) the value  
    for lookupCtlOperStatus MUST be transitioned to  
    completed(3)."  
::= { lookupCtlEntry 5 }

lookupCtlTime OBJECT-TYPE

STATUS           current  
DESCRIPTION  
    "Reports the number of milliseconds that a lookup  
    operation required to be completed at a remote host.  
    Completed means operation failure as well as  
    success."  
::= { lookupCtlEntry 6 }

lookupCtlRc OBJECT-TYPE  
SYNTAX           Integer32  
MAX-ACCESS       read-only  
STATUS           current  
DESCRIPTION  
    "The system specific return code from a lookup  
    operation.  All implementations MUST return a value  
    of 0 for this object when the remote lookup  
    operation succeeds.  A non-zero value for this  
    objects indicates failure.  It is recommended that  
    implementations that support errno use it as the  
    value of this object to aid a management  
    application in determining the cause of failure."  
::= { lookupCtlEntry 7 }

## lookupCtlRowStatus OBJECT-TYPE

SYNTAX RowStatus  
MAX-ACCESS read-create  
STATUS current

## DESCRIPTION

"This object allows entries to be created and deleted in the lookupCtlTable.

A remote lookup operation is started when an entry in this table is created via an SNMP SET request and the entry is activated. This occurs by setting the value of this object to CreateAndGo(4) during row creation or by setting this object to active(1) after the row is created.

A value MUST be specified for lookupCtlTargetAddress prior to a transition to active(1) state being accepted.

A remote lookup operation starts when its entry first becomes active(1). Transitions in and out of active(1) state have no effect on the operational behavior of a remote lookup operation, with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active remote lookup operation.

The operational state of a remote lookup operation can be determined by examination of its lookupCtlOperStatus object."

## REFERENCE

"See definition of RowStatus in [RFC 2579](#),  
'Textual Conventions for SMIV2.'"  
 ::= { lookupCtlEntry 8 }

## -- Lookup Results Table

## lookupResultsTable OBJECT-TYPE

SYNTAX SEQUENCE OF LookupResultsEntry  
MAX-ACCESS not-accessible  
STATUS current

## DESCRIPTION

"Defines the Lookup Results Table for providing the capability of determining the results of a operation at a remote host.

One or more entries are added to the lookupResultsTable when a lookup operation, as reflected by an lookupCtlEntry, completes successfully. All entries related to a successful lookup operation MUST be added to the lookupResultsTable at the same time that the associating lookupCtlOperStatus object is transitioned to completed(2).

The number of entries added depends on the results determined for a particular lookup operation. All entries associated with an lookupCtlEntry are removed when the lookupCtlEntry is deleted.

A remote host can be multi-homed and have more than one IP address associated with it (gethostbyname results) and/or it can have more than one symbolic name (gethostbyaddr results).

The gethostbyaddr function is called with a host address as its parameter and is used primarily to determine a symbolic name to associate with the host address. Entries in the lookupResultsTable MUST be made for each host name returned. The official host name MUST be assigned a lookupResultsIndex of 1.

The gethostbyname function is called with a symbolic host name and is used primarily to retrieve a host address. If possible the primary host address SHOULD be assigned a lookupResultsIndex of 1."

## 5.0 Security Considerations

Certain management information in the MIBs defined by this document may be considered sensitive in some network environments. Therefore, authentication of received SNMP requests and controlled access to management information SHOULD be employed in such environments. The method for this authentication is a function of the SNMP Administrative Framework, and has not been expanded by this MIB.

To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (VACM) defined in RFC 2575 [11] for tables in which multiple users may need to independently create or modify entries, the initial index is used as an "owner index". Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

All entries in related tables belonging to a particular user will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the "column" subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask "wildcarding" the column subidentifier. More elaborate configurations are possible. The VACM access control mechanism described above provides control.

In general, both the ping and traceroute functions when used excessively are considered a form of system attack. In the case of ping sending a system requests too often can negatively effect its performance or attempting to connect to what is supposed to be an unused port can be very unpredictable. Excessive use of the

traceroute capability can like ping negatively affect system performance. In insecure environments it is RECOMMENDED that the MIBs defined within this memo not be supported.

## 6.0 Intellectual Property

The IETF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on the IETF's procedures with respect to rights in standards-track and standards-related documentation can be found in [BCP-11](#). Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF Secretariat.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this standard. Please address the information to the IETF Executive Director.
