Definitions of Managed Objects for IP Storage User Identity Authorization

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

#### Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP-based internets. In particular, it defines objects for managing user identities and the names, addresses, and credentials required manage access control, for use with various protocols. This document was motivated by the need for the configuration of authorized user identities for the iSCSI protocol, but has been extended to be useful for other protocols that have similar requirements. It is important to note that this MIB module provides only the set of identities to be used within access lists; it is the responsibility of other MIB modules making use of this one to tie them to their own access lists or other authorization control methods.

## 1. Introduction

This MIB module will be used to configure and/or look at the configuration of user identities and their credential information. For the purposes of this MIB module, a "user" identity does not need to be an actual person; a user can also be a host, an application, a cluster of hosts, or any other identifiable entity that can be authorized to access a resource.

Most objects in this MIB module have a MAX-ACCESS of read-create; this module is intended to allow configuration of user identities and their names, addresses, and credentials. MIN-ACCESS for all objects is read-only for those implementations that configure through other means, but require the ability to monitor user identities.

## 2. Specification of Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

## 3. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

# 4. Relationship to Other MIB Modules

The IPS-AUTH-MIB module does not directly address objects within other modules. The identity address objects contain IPv4, IPv6, or other address types, and as such they may be indirectly related to objects within the IP [RFC4293] MIB module.

This MIB module does not provide actual authorization or access control lists; it provides a means to identify entities that can be included in other authorization lists. This should generally be done in MIB modules that reference identities in this one. It also does not cover login or authentication failure statistics or

Bakke & Muchow Standards Track [Page 3]

notifications, as these are all fairly application specific and are not generic enough to be included here.

The user identity objects within this module are typically referenced from other modules by a RowPointer within that module. A module containing resources for which it requires a list of authorized user identities may create such a list, with a single RowPointer within each list element pointing to a user identity within this module. This is neither required nor restricted by this MIB module.

## 5. Relationship to the USM MIB Module

The User-based Security Model (USM) [RFC3414] also defines the concept of a user, defining authentication and privacy protocols and their credentials. The definition of USM includes the SNMP-USER-BASED-SM-MIB module allows configuration of SNMPv3 user credentials to protect SNMPv3 messages. Although USM's users are not related to the user identities managed by the IPS-AUTH-MIB module defined in this document, USM will often be implemented on the same system as the IPS-AUTH-MIB module, with the SNMP-USER-BASED-SM-MIB module used to manage the security protecting SNMPv3 messages, including those that access the IPS-AUTH-MIB module.

The term "user" in this document is distinct from an SNMPv3 user and is intended to include, but is not limited to, users of IP storage devices. A "user" in this document is a collection of user names (unique identifiers), user addresses, and credentials that can be used together to determine whether an entity should be allowed access to a resource. Each user can have multiple names, addresses, and credentials. As a result, this MIB module is particularly suited to managing users of storage resources, which are typically given access control lists consisting of potentially multiple identifiers, addresses, and credentials. This MIB module provides for authorization lists only and does not include setting of data privacy parameters.

In contrast, an SNMPv3 user as defined in [RFC3414] has exactly one user-name, one authentication protocol, and one privacy protocol, along with their associated information and SNMP-specific information, such as an engine ID. These objects are defined to support exactly the information needed for SNMPv3 security.

For the remainder of this document, the term "user" means an IPS-AUTH-MIB user identity.

Bakke & Muchow Standards Track [Page 4]

## 6. Relationship to SNMP Contexts

Each non-scalar object in the IPS-AUTH-MIB module is indexed first by an instance. Each instance is a collection of identities that can be used to authorize access to a resource. The use of an instance works well with partitionable or hierarchical devices and fits in logically with other management schemes. Instances do not replace SNMP contexts; however, they do provide a very simple way to assign a collection of identities within a device to one or more SNMP contexts, without having to do so for each identity's row.

#### 7. Discussion

This MIB module structure is intended to allow the configuration of a list of user identities, each with a list of names, addresses, credentials, and certificates that, when combined, will distinguish that identity.

The IPS-AUTH-MIB module is structured around two primary "objects", the authorization instance and the identity, which serve as containers for the remainder of the objects. This section contains a brief description of the "object" hierarchy and a description of each object, followed by a discussion of the actual SNMP table structure within the objects.

# 7.1. Authorization MIB Object Model

The top-level object in this structure is the authorization instance, which "contains" all of the other objects. The indexing hierarchy of this module looks like:

# ipsAuthInstance

- -- A distinct authorization entity within the managed system.
- -- Most implementations will have just one of these. ipsAuthIdentity
  - -- A user identity, consisting of a set of identity names,
    - -- addresses, and credentials reflected in the following
    - -- objects:

# ipsAuthIdentityName

- -- A name for a user identity. A name should be globally
- -- unique, and unchanging over time. Some protocols may
- -- not require this one.

#### ipsAuthIdentityAddress

- -- An address range, typically but not necessarily an
- -- IPv4, IPv6, or Fibre Channel address range, at which
- -- the identity is allowed to reside.

# ${\tt ipsAuthCredential}$

-- A single credential, such as a CHAP username,

Bakke & Muchow Standards Track [Page 5]

-- which can be used to verify the identity.
ipsAuthCredChap
 -- CHAP-specific attributes for an ipsAuthCredential
ipsAuthCredSrp
 -- SRP-specific attributes
ipsAuthCredKerberos
 -- Kerberos-specific attributes

Each identity contains the information necessary to identify a particular end-point that wishes to access a service, such as iSCSI.

An identity can contain multiple names, addresses, and credentials. Each of these names, addresses, and credentials exists in its own row. If multiple rows of one of these three types are present, they are treated in an "OR" fashion; an entity to be authorized need only match one of the rows. If rows of different types are present (e.g., a name and an address), these are treated in an "AND" fashion; an entity to be authorized must match at least one row from each category. If there are no rows present of a category, this category is ignored.

For example, if an ipsAuthIdentity contains two rows of ipsAuthIdentityAddress, one row of ipsAuthCredential, and no rows of ipsAuthIdentityName, an entity must match the Credential row and at least one of the two Address rows to match the identity.

Index values such as ipsAuthInstIndex and ipsAuthIdentIndex are referenced in multiple tables, and rows can be added and deleted. An implementation should therefore attempt to keep all index values persistent across reboots; index values for rows that have been deleted must not be reused before a reboot.

#### 7.2. ipsAuthInstance

The ipsAuthInstanceAttributesTable is the primary table of the IPS-AUTH-MIB module. Every other table entry in this module includes the index of an ipsAuthInstanceAttributesEntry as its primary index. An authorization instance is basically a managed set of identities.

Many implementations will include just one authorization instance row in this table. However, there will be cases where multiple rows in this table may be used:

- A large system may be "partitioned" into multiple, distinct virtual systems, perhaps sharing the SNMP agent but not their lists of identities. Each virtual system would have its own authorization instance.

Bakke & Muchow Standards Track [Page 6]

- A set of stackable systems, each with its own set of identities, may be represented by a common SNMP agent. Each individual system would have its own authorization instance.
- Multiple protocols, each with its own set of identities, may exist within a single system and be represented by a single SNMP agent. In this case, each protocol may have its own authorization instance.

An entry in this table is often referenced by its name (ipsAuthInstDescr), which should be displayed to the user by the management station. When an implementation supports only one entry in this table, the description may be returned as a zero-length string.

#### 7.3. ipsAuthIdentity

The ipsAuthIdentAttributesTable contains one entry for each configured user identity. The identity contains only a description of what the identity is used for; its attributes are all contained in other tables, since they can each have multiple values.

Other MIB modules containing lists of users authorized to access a particular resource should generally contain a RowPointer to the ipsAuthIdentAttributesEntry that will, if authenticated, be allowed access to the resource.

All other table entries make use of the indices to this table as their primary indices.

## 7.4. ipsAuthIdentityName

The ipsAuthIdentNameAttributesTable contains a list of UTF-8 names, each of which belongs to, and may be used to identify, a particular identity in the authIdentity table.

Implementations making use of the IPS-AUTH-MIB module may identify their resources by names, addresses, or both. A name is typically a unique (within the required scope), unchanging identifier for a resource. It will normally meet some or all of the requirements for a Uniform Resource Name [RFC1737], although a name in the context of this MIB module does not need to be a URN. Identifiers that typically change over time should generally be placed into the ipsAuthIdentityAddress table; names that have no uniqueness properties should usually be placed into the description attribute for the identity.

Bakke & Muchow Standards Track [Page 7]

An example of an identity name is the iSCSI Name, defined in [RFC3720]. Any other MIB module defining names to be used as ipsAuthIdentityName objects should specify how its names are unique, and the domain within which they are unique.

If this table contains no entries associated with a particular user identity, the implementation does not need to check any name parameters when verifying that identity. If the table contains multiple entries associated with a particular user identity, the implementation should consider a match with any one of these entries to be valid.

# 7.5. ipsAuthIdentityAddress

The ipsAuthIdentAddrAttributesTable contains a list of addresses at which the identity may reside. For example, an identity may be allowed access to a resource only from a certain IP address, or only if its address is in a certain range or set of ranges.

Each entry contains a starting and ending address. If a single address is desired in the list, both starting and ending addresses must be identical.

Each entry contains an AddrType attribute. This attribute contains an enumeration registered as an IANA Address Family type [IANA-AF]. Although many implementations will use IPv4 or IPv6 address types for these entries, any IANA-registered type may be used, as long as it makes sense to the application.

Matching any address within any range within the list associated with a particular identity is considered a valid match. If no entries are present in this list for a given identity, its address is automatically assumed to match the identity.

Netmasks are not supported, since an address range can express the same thing with more flexibility. An application specifying addresses using network masks may do so, and convert to and from address ranges when reading or writing this MIB module.

## 7.6. ipsAuthCredential

The ipsAuthCredentialAttributesTable contains a list of credentials, each of which may be used to verify a particular identity.

Bakke & Muchow Standards Track [Page 8]

Each credential contains an authentication method to be used, such as CHAP [RFC1994], SRP [RFC2945], or Kerberos [RFC4120]. This attribute contains an object identifier instead of an enumerated type, allowing other MIB modules to add their own authentication methods, without modifying this MIB module.

For each entry in this table, there will exist an entry in another table containing its attributes. The table in which to place the entry depends on the AuthMethod attribute:

- CHAP If the AuthMethod is set to the CHAP OID, an entry using the same indices as the ipsAuthCredential will exist in the ipsAuthCredChap table, which contains the CHAP username.
- SRP If the AuthMethod is set to the SRP OID, an entry using the same indices as the ipsAuthCredential will exist in the ipsAuthCredSrp table, which contains the SRP username.
- Kerberos If the AuthMethod is set to the Kerberos OID, an entry using the same indices as the ipsAuthCredential will exist in the ipsAuthCredKerberos table, which contains the Kerberos principal.
- Other If the AuthMethod is set to any OID not defined in this module, an entry using the same indices as the ipsAuthCredential entry should be placed in the other module that define whatever attributes are needed for that type of credential.

An additional credential type can be added to this MIB module by defining a new OID in the ipsAuthMethodTypes subtree, and defining a new table specific to that credential type.

# 7.7. IP, Fibre Channel, and Other Addresses

The IP addresses in this MIB module are represented by two attributes, one of type AddressFamilyNumbers, and the other of type AuthAddress. Each address can take on any of the types within the list of address family numbers; the most likely being IPv4, IPv6, or one of the Fibre Channel address types.

The type AuthAddress is an octet string. If the address family is IPv4 or IPv6, the format is taken from the InetAddress specified in [RFC4001]. If the address family is one of the Fibre Channel types, the format is identical to the FcNameIdOrZero type defined in [RFC4044].

Bakke & Muchow Standards Track [Page 9]

# 7.8. Descriptors: Using OIDs in Place of Enumerated Types

Some attributes, particularly the authentication method attribute, would normally require an enumerated type. However, implementations will likely need to add new authentication method types of their own, without extending this MIB module. To make this work, this module defines a set of object identities within ipsAuthDescriptors. Each of these object identities is basically an enumerated type.

Attributes that make use of these object identities have a value that is an OID instead of an enumerated type. These OIDs can either indicate the object identities defined in this module, or object identities defined elsewhere, such as in an enterprise MIB module. Those implementations that add their own authentication methods should also define a corresponding object identity for each of these methods within their own enterprise MIB module, and return its OID whenever one of these attributes is using that method.

# 7.9. Notifications

Monitoring of authentication failures and other notification events are outside the scope of this MIB module, as they are generally application specific. No notifications are provided or required.

Bakke & Muchow Standards Track [Page 10]

## 9. Security Considerations

## 9.1. MIB Security Considerations

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- o in the ipsAuthInstanceAttributesTable:
  - ipsAuthInstDescr could be modified to camouflage the existence
     of a rogue authorization instance;
- o in the ipsAuthIdentAttributesTable:
  - ipsAuthIdentDescription could be modified to camouflage the existence of a rogue identity;
  - ipsAuthIdentRowStatus could be modified to add or delete a rogue identity;
  - ipsAuthIdentStorageType could be modified to make temporary rows permanent, or permanent rows temporary;
- o in the ipsAuthIdentNameAttributesTable:
  - ipsAuthIdentName could be modified to change the name of an existing identity;
  - ipsAuthIdentNameRowStatus could be modified to add or delete a name of an existing identity;
  - ipsAuthIdentNameStorageType could be modified to make temporary rows permanent, or permanent rows temporary;
- o in the ipsAuthIdentAddrAttributesTable:
  - ipsAuthIdentAddrType could be modified to change the type of address checking performed;
  - ipsAuthIdentAddrStart could be modified to change the start of the allowed range;

- ipsAuthIdentAddrEnd could be modified to change the end of the allowed range;
- ipsAuthIdentAddrRowStatus could be modified to add or delete the checking of an address range;
- ipsAuthIdentAddrStorageType could be modified to make temporary rows permanent, or permanent rows temporary;
- o in the ipsAuthCredentialAttributesTable:
  - ipsAuthCredAuthMethod could be modified to change the type of authentication to be used;
  - ipsAuthCredRowStatus could be modified to add or delete checking of credentials;
  - ipsAuthCredStorageType could be modified to make temporary rows permanent, or permanent rows temporary;
- o in the ipsAuthCredChapAttributesTable:
  - ipsAuthCredChapUserName could be modified to change the CHAP
     user name for a credential;
  - ipsAuthCredChapRowStatus could be modified to add or delete CHAP attributes for credentials;
  - ipsAuthCredChapStorageType could be modified to make temporary rows permanent, or permanent rows temporary;
- o in the ipsAuthCredSrpAttributesTable:
  - ipsAuthCredSrpUserName could be modified to change the SRP user name for a credential;
  - ipsAuthCredSrpRowStatus could be modified to add or delete SRP attributes for credentials;
  - ipsAuthCredSrpStorageType could be modified to make temporary rows permanent, or permanent rows temporary;
- o in the ipsAuthCredKerbAttributesTable:
  - ipsAuthCredKerbPrincipal could be modified to change the Kerberos principal for a credential;

- ipsAuthCredKerbRowStatus could be modified to add or delete
   Kerberos attributes for credentials;
- ipsAuthCredKerbStorageType could be modified to make temporary rows permanent, or permanent rows temporary;

Note that removal of legitimate credentials can result in either denial of service or weakening the requirements for access of a particular service. Note also that some types of credentials, such as CHAP or SRP, also require passwords or verifiers to be associated with the credential. These are managed outside this MIB module.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

o All tables (specifically: ipsAuthInstanceAttributesTable, ipsAuthIdentAttributesTable, ipsAuthIdentNameAttributesTable, ipsAuthIdentAddrAttributesTable, ipsAuthCredentialAttributesTable, ipsAuthCredChapAttributesTable, ipsAuthCredSrpAttributesTable, and ipsAuthCredKerbAttributesTable) provide the ability to find out which names, addresses, and credentials would be required to access services on the managed system. If these credentials are easily spoofed (particularly the name or address), read access to this MIB module must be tightly controlled. When used with pointers from another MIB module to rows in the ipsAuthIdentAttributesTable, this MIB module provides information about which entities are authorized to connect to which entities.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPsec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementors consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an

Bakke & Muchow Standards Track [Page 37]

instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

In many implementations, the objects in this MIB module can be read and modified via other mechanisms or protocols in addition to this MIB module. For the system to be secure, other mechanisms that can read and modify the contents of this MIB module must also address the above issues, and handle the threats outlined in [RFC3411], section 1.4.

Given the sensitivity of information contained in this MIB module, it is strongly recommended that encryption (SNMPv3 with a securityLevel of authPriv [RFC3411]) be used for all access to objects in this MIB module.

## 9.2. Other Security Considerations

An identity consists of a set of names (e.g., an iSCSI Initiator Name), addresses (e.g., an IP address or Fibre Channel World Wide Name (WWN)), and credentials (e.g., a CHAP user name).

To match an identity, one must match:

- o One of the IdentNames belonging to the IdentIndex, unless there are no IdentNames for the IdentIndex, and
- o One of the IdentAddrs belonging to the IdentIndex, unless there are no IdentAddrs for the IdentIndex, and
- o One of the IdentCreds belonging to the IdentIndex, unless there are no Creds for the IdentIndex.

Note that if any of the above lists are empty for a given IdentIndex, any identifier of that type is considered to match the identity. The non-empty lists will still be checked. For example, if the IdentAddrs list is empty for the IndentIndex, but there are entries in IdentNames and IdentCreds, any address will be considered a match, as long as the offered name and credential match one of the IdentNames and IdentCreds, respectively.

This leaves a possible security window while adding and removing entries from one of these lists. For example, an identity could consist of no IdentNames, no IdentAddrs, and exactly one IdentCred. If that IdentCred was to be updated, several methods could be used:

- o The UserName or Principal could be simply written in the appropriate table, if the credential's type remained the same (recommended).
- o The new credential could be added, then the old deleted (recommended).
- o The new credential could be added, and the old deleted in the same SNMP request (recommended, but do the add first).
- o The old credential could be deleted, then the new added (Don't use!).

Of the above methods, the last leaves a window in which the list is empty, possibly allowing unconstrained access to the resource making use of this MIB. This method should never be used for Names, Addrs, or Creds.

The use of the third method, adding and deleting within the same request, should be used with care. It is recommended that within the request, the add be done first. Otherwise, an implementation may attempt to perform these operations in order, potentially leaving a window.

The first two methods are recommended.

Care must also be taken when updating the IdentAddrs for an identity. Each IdentAddr specifies a range of addresses that match the identity, and has an address type, starting address, and ending address. Modifying these one at a time can open a temporary window where a larger range of addresses are allowed. For example, a single address is specified using IdentAddrType = ipv4, IdentAddrStart = IdentAddrEnd = 192.0.2.5. We want to update this to specify the single address 192.0.2.34. If the end address is updated first, we temporarily allow the range 192.0.2.5 .. 192.0.2.34, which is not what we want. Similarly, if we change from 192.0.2.34 back to 192.0.2.5, and we update IdentAddrStart first, we end up with the range again. To handle this, an application must either:

- o update both IdentAddrStart and IdentAddrEnd in the same SNMP set request, or
- o add the new IdentAddrStart and IdentAddrEnd with a new IdentAddrIndex, then delete the old one, using the methods shown before.

Since the value of IdentAddrType specifies the formats of IdentAddrStart and IdentAddrEnd, modification of IdentAddrType is not allowed for an existing row.

#### 10. IANA Considerations

The IANA has assigned a MIB OID number under the mib-2 branch for the IPS-AUTH-MIB.
