Definitions of Managed Objects for IEEE 802.3 Repeater Devices

### Status of this Memo

This RFC specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" for the standardization state and status of this protocol. Distribution of this memo is unlimited.

# Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it defines objects for managing IEEE 802.3 10 Mb/second baseband repeaters, sometimes referred to as "hubs."

### 1. The Network Management Framework

The Internet-standard Network Management Framework consists of three components. They are:

- o STD 16, RFC 1155 which defines the SMI, the mechanisms used for describing and naming objects for the purpose of management. STD 16, RFC 1212 defines a more concise description mechanism, which is wholly consistent with the SMI.
- o STD 17, RFC 1213 defines MIB-II, the core set of managed objects for the Internet suite of protocols.
- o STD 15, RFC 1157 which defines the SNMP, the protocol used for network access to managed objects.

The Framework permits new objects to be defined for the purpose of experimentation and evaluation.

### 1.1. Object Definitions

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the subset of Abstract Syntax Notation One (ASN.1) defined in the SMI. In particular, each object object type is named by an OBJECT IDENTIFIER, an administratively assigned name. The object type together with an object instance serves to uniquely identify a specific instantiation of the object. For human convenience, we often use a textual string, termed the descriptor, to refer to the object type.

### 2. Overview

Instances of the object types defined in this memo represent attributes of an IEEE 802.3 (Ethernet-like) repeater, as defined by Section 9, "Repeater Unit for 10 Mb/s Baseband Networks" in the IEEE 802.3/ISO 8802-3 CSMA/CD standard [7].

These Repeater MIB objects may be used to manage non-standard repeater-like devices, but defining objects to describe

implementation-specific properties of non-standard repeater-like devices is outside the scope of this memo.

The definitions presented here are based on the IEEE draft standard P802.3K, "Layer Management for 10 Mb/s Baseband Repeaters" [8]. Implementors of these MIB objects should note that [8] explicitly describes when, where, and how various repeater attributes are measured. The IEEE document also describes the effects of repeater actions that may be invoked by manipulating instances of the MIB objects defined here.

The counters in this document are defined to be the same as those counters in the IEEE 802.3 Repeater Management draft, with the intention that the same instrumentation can be used to implement both the IEEE and IETF management standards.

### 2.1. Terminology

### 2.1.1. Repeaters, Hubs and Concentrators

In late 1988, the IEEE 802.3 Hub Management task force was chartered to define managed objects for both 802.3 repeaters and the proposed 10BASE-FA synchronous active stars. The term "hub" was used to cover both repeaters and active stars.

In March, 1991, the active star proposal was dropped from the 10BASE-F draft. Subsequently the 802.3 group changed the name of the task force to be the IEEE 802.3 Repeater Management Task Force, and likewise renamed their draft.

The use of the term "hub" has led to some confusion, as the terms "hub," "intelligent hub," and "concentrator" are often used to indicate a modular chassis with plug-in modules that provide generalized LAN/WAN connectivity, often with a mix of 802.3 repeater, token ring, and FDDI connectivity, internetworked by bridges, routers, and terminal servers.

To be clear that this work covers the management of IEEE 802.3 repeaters only, the editors of this MIB definitions document chose to call this a "Repeater MIB" instead of a "Hub MIB."

# 2.1.2. Repeaters, Ports, and MAUs

The following text roughly defines the terms "repeater," "port," and "MAU" as used in the context of this memo. This text is imprecise and omits many technical details. For a more complete and precise definition of these terms, refer to Section 9 of [7].

An IEEE 802.3 repeater connects "Ethernet-like" media segments together to extend the network length and topology beyond what can be achieved with a single coax segment. It can be pictured as a star structure with two or more input/output ports. The diagram below illustrates a 6-port repeater:

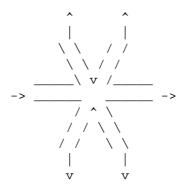

Figure 1. Repeater Unit

All the stations on the media segments connected to a given repeater's ports participate in a single collision domain. A packet transmitted by any of these stations is seen by all of these stations.

Data coming in on any port in the repeater is transmitted out through each of the remaining n-1 ports. If data comes in to the repeater on two or more ports simultaneously or the repeater detects a collision on the incoming port, the repeater transmits a jamming signal out on all ports for the duration of the collision.

A repeater is a bit-wise store-and-forward device. It is differentiated from a bridge (a frame store-and-forward device) in that it is primarily concerned with carrier sense and data bits, and does not make data-handling decisions based on the legality or contents of a packet. A repeater retransmits data bits as they are received. Its data FIFO holds only enough bits to make sure that the FIFO does not underflow when the data rate of incoming bits is slightly slower than the repeater's transmission rate.

A repeater is not an end-station on the network, and does not count toward the overall limit of 1024 stations. A repeater has no MAC address associated with it, and therefore packets may not be addressed to the repeater or to its ports. (Packets may be addressed to the MAC address of a management entity that is monitoring a repeater. This management entity may or may not be connected to the network through one of the repeater's ports. How the management entity obtains information about the activity on the repeater is an

implementation issue, and is not discussed in this memo.)

A repeater is connected to the network with Medium Attachment Units (MAUs), and sometimes through Attachment Unit Interfaces (AUIs) as well. ("MAUs" are also known as transceivers, and an "AUI" is the same as a 15-pin Ethernet or DIX connector.)

The 802.3 standard defines a "repeater set" as the "repeater unit" plus its associated MAUs (and AUIs if present). The "repeater unit" is defined as the portion of the repeater set that is inboard of the physical media interfaces. The MAUs may be physically separate from the repeater unit, or they may be integrated into the same physical package.

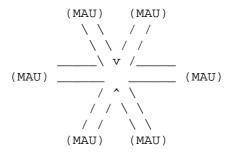

Figure 2. Repeater Set

The most commonly-used MAUs are the 10BASE-5 (AUI to thick "yellow" coax), 10BASE-2 (BNC to thin coax), 10BASE-T (unshielded twisted-pair), and FOIRL (asynchronous fiber optic inter-repeater link, which is being combined into the 10BASE-F standard as 10BASE-FL). The draft 10BASE-F standard also includes the definition for a new synchronous fiber optic attachment, known as 10BASE-FB.

It should be stressed that the repeater MIB being defined by the IEEE covers only the repeater unit management – it does not include management of the MAUs that form the repeater set. The IEEE recognizes that MAU management should be the same for MAUs connected to end-stations (DTEs) as it is for MAUs connected to repeaters. This memo follows the same strategy; the definition of management information for MAUs is being addressed in a separate memo.

# 2.1.3. Ports and Groups

Repeaters are often implemented in modular "concentrators," where a card cage holds several field-replaceable cards. Several cards may form a single repeater unit, with each card containing one or more of the repeater's ports. Because of this modular architecture, users typically identify these repeater ports with a card number plus the

port number relative to the card, e.g., Card 3, Port 11.

To support this modular numbering scheme, this document follows the example of the IEEE Repeater Management draft [8], allowing an implementor to separate the ports in a repeater into "groups", if desired. For example, an implementor might choose to represent field-replaceable units as groups of ports so that the port numbering would match the modular hardware implementation.

This group mapping is recommended but optional. An implementor may choose to put all of a modular repeater's ports into a single group, or to divide the ports into groups that do not match physical divisions.

The object rptrGroupCapacity, which has a maximum value of 1024, indicates the maximum number of groups that a given repeater may contain. The value of rptrGroupCapacity must remain constant from one management restart to the next.

Each group within the repeater is uniquely identified by a group number in the range 1..rptrGroupCapacity. Groups may come and go without causing a management reset, and may be sparsely numbered within the repeater. For example, in a 12- card cage, cards 3, 5, 6, and 7 may together form a single repeater, and the implementor may choose to number them as groups 3, 5, 6, and 7, respectively.

The object rptrGroupPortCapacity, which also has a maximum value of 1024, indicates the maximum number of ports that a given group may contain. The value of rptrGroupPortCapacity must not change for a given group. However, a group may be deleted from the repeater and replaced with a group containing a different number of ports. The value of rptrGroupLastOperStatusChange will indicate that a change took place.

Each port within the repeater is uniquely identified by a combination of group number and port number, where port number is an integer in the range 1..rptrGroupPortCapacity. As with groups within a repeater, ports within a group may be sparsely numbered. Likewise, ports may come and go within a group without causing a management reset.

## 2.1.4. Internal Ports and MAUs

Repeater ports may be thought of as sources of traffic into the repeater. In addition to the externally visible ports mentioned above, such as those with 10BASE-T MAUs, or AUI ports with external transceivers, some implementations may have internal ports that are not obvious to the end-user but are nevertheless sources of traffic

into the repeater. Examples include internal management ports, through which an agent communicates, and ports connecting to a backplane internal to the implementation.

Some implementations may not manage all of a repeater's ports. For managed ports, there must be entries in the port table; unmanaged ports will not show up in the table.

It is the decision of the implementor to select the appropriate group(s) in which to place internal ports. GroupCapacity for a given group always reflects the number of MANAGED ports in that group.

If some ports are unmanaged such that not all packet sources are represented by managed ports, then the sum of the input counters for the repeater will not equal the actual output of the repeater.

### 2.2. Supporting Functions

The IEEE 802.3 Hub Management draft [8] defines the following seven functions and seven signals used to describe precisely when port counters are incremented. The relationship between the functions and signals is shown in Figure 3.

The CollisionEvent, ActivityDuration, CarrierEvent, FramingError, OctetCount, FCSError, and SourceAddress output signals defined here are not retrievable MIB objects, but rather are concepts used in defining the MIB objects. The inputs are defined in Section 9 of the IEEE 802.3 standard [7].

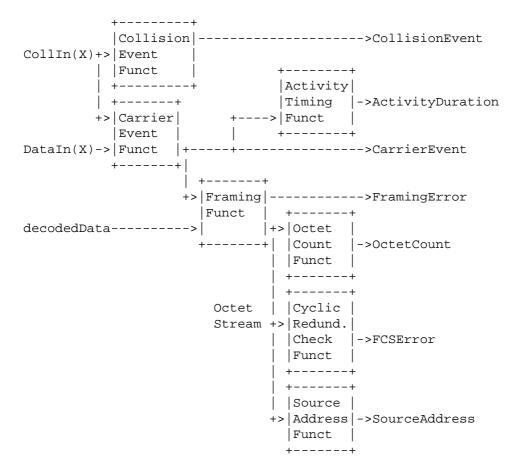

Figure 3. Port Functions Relationship

Collision Event Function: The collision event function asserts the CollisionEvent signal when the Collin(X) variable has the value SQE. The CollisionEvent signal remains asserted until the assertion of any CarrierEvent signal due to the reception of the following event.

Carrier Event Function: The carrier event function asserts the CarrierEvent signal when the repeater exits the IDLE state, Fig 9-2 [7], and the port has been determined to be port N. It deasserts the CarrierEvent signal when, for a duration of at least Carrier Recovery Time (Ref: 9.5.6.5 [7]), both the DataIn(N) variable has the value II and the CollIn(N) variable has the value -SQE. The value N is the port assigned at the time of transition from the IDLE state.

Framing Function: The framing function recognizes the boundaries of an incoming frame by monitoring the CarrierEvent signal and the

decoded data stream. Data bits are accepted while the CarrierEvent signal is asserted. The framing function strips preamble and start of frame delimiter from the received data stream. The remaining bits are aligned along octet boundaries. If there is not an integral number of octets, then FramingError shall be asserted. The FramingError signal is cleared upon the assertion of the CarrierEvent signal due to the reception of the following event.

Activity Timing Function: The activity timing function measures the duration of the assertion of the CarrierEvent signal. This duration value must be adjusted by removing the value of Carrier Recovery Time (Ref: 9.5.6.5 [7]) to obtain the true duration of activity on the network. The output of the Activity Timing function is the ActivityDuration value, which represents the duration of the CarrierEvent signal as expressed in units of bit times.

Octet Counting Function: The octet counting function counts the number of complete octets received from the output of the framing function. The output of the octet counting function is the OctetCount value. The OctetCount value is reset to zero upon the assertion of the CarrierEvent signal due to the reception of the following event.

Cyclic Redundancy Check Function: The cyclic redundancy check function verifies that the sequence of octets output by the framing function contains a valid frame check sequence field. The frame check sequence field is the last four octets received from the output of the framing function. The algorithm for generating an FCS from the octet stream is specified in 3.2.8 [7]. If the FCS generated according to this algorithm is not the same as the last four octets received from the framing function then the FCSError signal is asserted. The FCSError signal is cleared upon the assertion of the CarrierEvent signal due to the reception of the following event.

Source Address Function: The source address function extracts octets from the stream output by the framing function. The seventh through twelfth octets shall be extracted from the octet stream and output as the SourceAddress variable. The SourceAddress variable is set to an invalid state upon the assertion of the CarrierEvent signal due to the reception of the following event.

### 2.3. Structure of MIB

Objects in this MIB are arranged into MIB groups. Each MIB group is organized as a set of related objects.

### 2.3.1. The Basic Group Definitions

This mandatory group contains the objects which are applicable to all repeaters. It contains status, parameter and control objects for the repeater as a whole, the port groups within the repeater, as well as for the individual ports themselves.

### 2.3.2. The Monitor Group Definitions

This optional group contains monitoring statistics for the repeater as a whole and for individual ports.

# 2.3.3. The Address Tracking Group Definitions

This optional group contains objects for tracking the MAC addresses of the DTEs attached to the ports of the repeater.

## 2.4. Relationship to Other MIBs

It is assumed that a repeater implementing this MIB will also implement (at least) the 'system' group defined in MIB-II [3].

### 2.4.1. Relationship to the 'system' group

In MIB-II, the 'system' group is defined as being mandatory for all systems such that each managed entity contains one instance of each object in the 'system' group. Thus, those objects apply to the entity even if the entity's sole functionality is management of a repeater.

### 2.4.2. Relationship to the 'interfaces' group

In MIB-II, the 'interfaces' group is defined as being mandatory for all systems and contains information on an entity's interfaces, where each interface is thought of as being attached to a the Internet suite of protocols.)

This Repeater MIB uses the notion of ports on a repeater. The concept of a MIB-II interface has NO specific relationship to a repeater's port. Therefore, the 'interfaces' group applies only to the one (or more) network interfaces on which the entity managing the repeater sends and receives management protocol operations, and does not apply to the repeater's ports.

This is consistent with the physical-layer nature of a repeater. A repeater is a bitwise store-and-forward device. It recognizes activity and bits, but does not process incoming data based on any packet-related information (such as checksum or addresses). A

repeater has no MAC address, no MAC implementation, and does not pass packets up to higher-level protocol entities for processing.

(When a network management entity is observing the repeater, it may appear as though the repeater is passing packets to a higher-level protocol entity. However, this is only a means of implementing management, and this passing of management information is not part of the repeater functionality.)

### 2.5. Textual Conventions

The datatype MacAddress is used as a textual convention in this document. This textual convention has NO effect on either the syntax nor the semantics of any managed object. Objects defined using this convention are always encoded by means of the rules that define their primitive type. Hence, no changes to the SMI or the SNMP are necessary to accommodate this textual convention which is adopted merely for the convenience of readers.

rptrGroupCapacity OBJECT-TYPE
   SYNTAX INTEGER (1..1024)
   ACCESS
            read-only
    STATUS mandatory
   DESCRIPTION
            "The rptrGroupCapacity is the number of groups
            that can be contained within the repeater. Within
            each managed repeater, the groups are uniquely
            numbered in the range from 1 to rptrGroupCapacity.
            Some groups may not be present in the repeater, in
            which case the actual number of groups present
            will be less than rptrGroupCapacity. The number
            of groups present will never be greater than
            rptrGroupCapacity.
            Note: In practice, this will generally be the
            number of field-replaceable units (i.e., modules,
            cards, or boards) that can fit in the physical
            repeater enclosure, and the group numbers will
            correspond to numbers marked on the physical
            enclosure."
   REFERENCE
            "Reference IEEE 802.3 Rptr Mgt, 19.2.3.2,
            aRepeaterGroupCapacity."
    ::= { rptrRptrInfo 1 }
rptrOperStatus OBJECT-TYPE
```

```
SYNTAX INTEGER {
                                  -- undefined or unknown status
               other(1),
                                  -- no known failures
               generalFailure(6) -- failure, unspecified type
            read-only
   ACCESS
   STATUS
           mandatory
   DESCRIPTION
           "The rptrOperStatus object indicates the
           operational state of the repeater. The
           rptrHealthText object may be consulted for more
           specific information about the state of the
           repeater's health.
           In the case of multiple kinds of failures (e.g.,
           repeater failure and port failure), the value of
           this attribute shall reflect the highest priority
           failure in the following order, listed highest
           priority first:
               rptrFailure(3)
               groupFailure(4)
               portFailure(5)
               generalFailure(6)."

   DESCRIPTION
           "The health text object is a text string that
           provides information relevant to the operational
           state of the repeater. Agents may use this string
           to provide detailed information on current
           failures, including how they were detected, and/or
           instructions for problem resolution. The contents
           are agent-specific."
   REFERENCE
           "Reference IEEE 802.3 Rptr Mgt, 19.2.3.2,
           aRepeaterHealthText."
    ::= { rptrRptrInfo 3 }
```

```
rptrReset OBJECT-TYPE
   SYNTAX INTEGER {
                 noReset(1),
                 reset(2)
    ACCESS
             read-write
    STATUS
             mandatory
    DESCRIPTION
            "Setting this object to reset(2) causes a
            transition to the START state of Fig 9-2 in
            section 9 [IEEE 802.3 Std].
            Setting this object to noReset(1) has no effect.
            The agent will always return the value noReset(1)
            when this object is read.
            After receiving a request to set this variable to
            reset(2), the agent is allowed to delay the reset
            for a short period. For example, the implementor
            may choose to delay the reset long enough to allow
            the SNMP response to be transmitted. In any
            event, the SNMP response must be transmitted.
            This action does not reset the management counters
            defined in this document nor does it affect the
            portAdminStatus parameters. Included in this
            action is the execution of a disruptive Self-Test
            with the following characteristics: a) The nature
            of the tests is not specified. b) The test resets
            the repeater but without affecting management
            information about the repeater. c) The test does
            not inject packets onto any segment. d) Packets
            received during the test may or may not be
            transferred. e) The test does not interfere with
            management functions.
            After performing this self-test, the agent will
            update the repeater health information (including
            rptrOperStatus and rptrHealthText), and send a
            rptrHealth trap."
   REFERENCE
            "Reference IEEE 802.3 Rptr Mgt, 19.2.3.3,
            acResetRepeater."
    ::= { rptrRptrInfo 4 }
```

noSelfTest(1),

selfTest(2)

```
ACCESS
             read-write
   STATUS
            mandatory
   DESCRIPTION
            "Setting this object to selfTest(2) causes the
            repeater to perform a agent-specific, non-
           disruptive self-test that has the following
           characteristics: a) The nature of the tests is
           not specified. b) The test does not change the
           state of the repeater or management information
           about the repeater. c) The test does not inject
           packets onto any segment. d) The test does not
           prevent the relay of any packets. e) The test
           does not interfere with management functions.
           After performing this test, the agent will update
           the repeater health information (including
           rptrOperStatus and rptrHealthText) and send a
           rptrHealth trap.
           Note that this definition allows returning an
            'okay' result after doing a trivial test.
           Setting this object to noSelfTest(1) has no
           effect. The agent will always return the value
           noSelfTest(1) when this object is read."

    STATUS
            mandatory
    DESCRIPTION
            "Setting this object to disabled(2) disables the
           port. A disabled port neither transmits nor
           receives. Once disabled, a port must be
           explicitly enabled to restore operation. A port
           which is disabled when power is lost or when a
           reset is exerted shall remain disabled when normal
           operation resumes.
```

The admin status takes precedence over autopartition and functionally operates between the auto-partition mechanism and the AUI/PMA.

Setting this object to enabled(1) enables the port and exerts a BEGIN on the port's auto-partition state machine.

(In effect, when a port is disabled, the value of rptrPortAutoPartitionState for that port is frozen until the port is next enabled. When the port

```
becomes enabled, the rptrPortAutoPartitionState
            becomes notAutoPartitioned(1), regardless of its
           pre-disabling state.)"

#### DESCRIPTION

"This counter is incremented by one for each frame received on this port with the FCSError and FramingError signals asserted and CollisionEvent signal deasserted and whose OctetCount is greater than or equal to minFrameSize and less than or equal to maxFrameSize (Ref: IEEE 802.3 Std, 4.4.2.1). If rptrMonitorPortAlignmentErrors is incremented then the rptrMonitorPortFCSErrors Counter shall not be incremented for the same frame.

The approximate minimum time for rollover of this counter is 80 hours."

### REFERENCE

rptrMonitorPortFrameTooLongs OBJECT-TYPE

SYNTAX Counter
ACCESS read-only
STATUS mandatory
DESCRIPTION

"This counter is incremented by one for each frame received on this port whose OctetCount is greater than maxFrameSize (Ref: 4.4.2.1, IEEE 802.3 Std). If rptrMonitorPortFrameTooLongs is incremented then neither the rptrMonitorPortAlignmentErrors nor the rptrMonitorPortFCSErrors counter shall be incremented for the frame.

The approximate minimum time for rollover of this counter is 61 days."

### REFERENCE

### rptrMonitorPortShortEvents OBJECT-TYPE

SYNTAX Counter
ACCESS read-only
STATUS mandatory
DESCRIPTION

"This counter is incremented by one for each CarrierEvent on this port with ActivityDuration less than ShortEventMaxTime. ShortEventMaxTime is greater than 74 bit times and less than 82 bit

times. ShortEventMaxTime has tolerances included to provide for circuit losses between a conformance test point at the AUI and the measurement point within the state machine.

Note: shortEvents may indicate externally generated noise hits which will cause the repeater to transmit Runts to its other ports, or propagate a collision (which may be late) back to the transmitting DTE and damaged frames to the rest of the network.

Implementors may wish to consider selecting the ShortEventMaxTime towards the lower end of the allowed tolerance range to accommodate bit losses suffered through physical channel devices not budgeted for within this standard.

The approximate minimum time for rollover of this counter is 16 hours."

#### REFERENCE

"Reference IEEE 802.3 Rptr Mgt, 19.2.6.2, aShortEvents."

::= { rptrMonitorPortEntry 8 }

rptrMonitorPortRunts OBJECT-TYPE

SYNTAX Counter
ACCESS read-only
STATUS mandatory

DESCRIPTION

"This counter is incremented by one for each CarrierEvent on this port that meets one of the following two conditions. Only one test need be made. a) The ActivityDuration is greater than ShortEventMaxTime and less than ValidPacketMinTime and the CollisionEvent signal is deasserted. b) The OctetCount is less than 64, the ActivityDuration is greater than ShortEventMaxTime and the CollisionEvent signal is deasserted. ValidPacketMinTime is greater than or equal to 552 bit times and less than 565 bit times.

An event whose length is greater than 74 bit times but less than 82 bit times shall increment either the shortEvents counter or the runts counter but not both. A CarrierEvent greater than or equal to 552 bit times but less than 565 bit times may or may not be counted as a runt.

ValidPacketMinTime has tolerances included to provide for circuit losses between a conformance test point at the AUI and the measurement point within the state machine.

Runts usually indicate collision fragments, a normal network event. In certain situations associated with large diameter networks a percentage of collision fragments may exceed ValidPacketMinTime.

The approximate minimum time for rollover of this counter is 16 hours."

DESCRIPTION

"This counter is incremented by one for any CarrierEvent signal on any port for which the CollisionEvent signal on this port is also asserted.

The approximate minimum time for rollover of this counter is 16 hours."

### REFERENCE

rptrMonitorPortLateEvents OBJECT-TYPE
 SYNTAX Counter

ACCESS read-only STATUS mandatory

DESCRIPTION

"This counter is incremented by one for each CarrierEvent on this port in which the CollIn(X) variable transitions to the value SQE (Ref: 9.6.6.2, IEEE 802.3 Std) while the ActivityDuration is greater than the LateEventThreshold. Such a CarrierEvent is counted twice, as both a collision and as a lateEvent.

The LateEventThreshold is greater than 480 bit times and less than 565 bit times. LateEventThreshold has tolerances included to permit an implementation to build a single threshold to serve as both the LateEventThreshold and ValidPacketMinTime threshold.

The approximate minimum time for rollover of this counter is 81 hours."

    ::= { rptrAddrTrackEntry 5 }
-- Traps for use by Repeaters
-- Traps are defined using the conventions in RFC 1215 [6].
rptrHealth TRAP-TYPE
   ENTERPRISE snmpDot3RptrMgt
   VARIABLES
              { rptrOperStatus }
   DESCRIPTION
            "The rptrHealth trap conveys information related
            to the operational status of the repeater. This
           trap is sent either when the value of
           rptrOperStatus changes, or upon completion of a
           non-disruptive test.
           The rptrHealth trap must contain the
           rptrOperStatus object. The agent may optionally
           include the rptrHealthText object in the varBind
           list. See the rptrOperStatus and rptrHealthText
           objects for descriptions of the information that
```

is sent.

The agent must throttle the generation of consecutive rptrHealth traps so that there is at least a five-second gap between traps of this type. When traps are throttled, they are dropped, not queued for sending at a future time. (Note that 'generating' a trap means sending to all configured recipients.)"

```
rptrGroupChange TRAP-TYPE
   ENTERPRISE snmpDot3RptrMgt
   VARIABLES { rptrGroupIndex }
   DESCRIPTION
```

"This trap is sent when a change occurs in the group structure of a repeater. This occurs only when a group is logically or physically removed from or added to a repeater. The varBind list contains the identifier of the group that was removed or added.

The agent must throttle the generation of consecutive rptrGroupChange traps for the same group so that there is at least a five-second gap between traps of this type. When traps are throttled, they are dropped, not queued for sending at a future time. (Note that 'generating' a trap means sending to all configured recipients.)"

## REFERENCE

"Reference IEEE 802.3 Rptr Mgt, 19.2.3.4, groupMapChange notification."

**::=** 2

```
rptrResetEvent TRAP-TYPE
    ENTERPRISE snmpDot3RptrMgt
    VARIABLES { rptrOperStatus }
    DESCRIPTION
```

"The rptrResetEvent trap conveys information related to the operational status of the repeater. This trap is sent on completion of a repeater reset action. A repeater reset action is defined as an a transition to the START state of Fig 9-2 in section 9 [IEEE 802.3 Std], when triggered by a management command (e.g., an SNMP Set on the rptrReset object).

The agent must throttle the generation of consecutive rptrResetEvent traps so that there is at least a five-second gap between traps of this type. When traps are throttled, they are dropped, not queued for sending at a future time. (Note that 'generating' a trap means sending to all configured recipients.)

The rptrResetEvent trap is not sent when the agent restarts and sends an SNMP coldStart or warmStart trap. However, it is recommended that a repeater agent send the rptrOperStatus object as an optional object with its coldStart and warmStart trap PDUs.

The rptrOperStatus object must be included in the varbind list sent with this trap. The agent may optionally include the rptrHealthText object as well."

#### REFERENCE

"Reference IEEE 802.3 Rptr Mgt, 19.2.3.4, hubReset notification."

**::=** 3

END

### 4. Changes from RFC 1368

- (1) Added section 2.1.4, "Internal Ports and MAUs," that defines internal ports and clarifies how they may or may not be managed.
- (2) Noted that the failure list for rptrOperStatus is ordered highest priority first.
- (3) Clarified rptrReset description to indicate that the agent may briefly delay the reset action.
- (4) For rptrReset, clarified the actions that the agent should take after performing the reset and self-test.
- (5) For rptrNonDisruptTest, similar change to (3).
- (6) Clarified that the rptrNonDisruptTest description allows returning "ok" after doing only a trivial test.
- $\hbox{(7)} \quad \hbox{\tt Deprecated rptrAddrTrackLastSourceAddress and defined a}\\$

replacement object that has a zero-length value until the first frame is seen on the port.

- (8) Clarified that rptrHealth trap is sent after rptrNonDisruptTest even if repeater health information doesn't change as a result of the test.
- (9) Clarified text on throttling traps.

### 5. Acknowledgments

This document is the work of the IETF Hub MIB Working Group. It is based on drafts of the IEEE 802.3 Repeater Management Task Force.
